PREFACE

Change detection & urban sprawl LULC is trending nowadays because due to urbanization most of the place's land cover features are changing. For analyzing the LULC we can classify images in supervised and unsupervised classification. In Supervised classification, we need to identify the features of land cover and thereafter we can use different methods of supervised classification with the help of software. But in unsupervised classification, we only use the method there is no need to identify the features, we command the software and the software does it on its own. But compared to unsupervised classification supervised classification is most useful and reliable nowadays.

Land Surface Temperature and Ground Air Temperature both are the parameters of climate. Both are dependent on sunlight directly and indirectly respectively. Sun firstly warms the land and land warms the ground air. LST can only be increased by the sun and an increase in LST can be harmful to the vegetation index of any particular area but on the other hand, air temperature relies on LST and some other parameters as well such as CFC, Polluted atmosphere, and many more things.
