PREFACE

Fake news is a widespread danger to information integrity and the welfare of society in the modern digital age. Acknowledging the pressing need to tackle this issue, this research initiative sets out to explore approaches for detecting fake news. This study tries to unravel the complicated nature of misinformation transmission by utilizing deep learning approaches, such as Feed Forward Neural Networks (FNN), CNN, LSTM networks. By means of rigorous data preprocessing, feature engineering, and model assessment, we want to provide stakeholders with strong instruments to differentiate between genuine and fraudulent news stories. This project report functions as a thorough record of our investigation, explaining the approaches taken, the knowledge acquired for countering false information.
